an improved procedure based on the intercept method of measuring the grain size of single phase microstructures has been developed that provides a quantitative description of the grain size yet is fast the procedure combines the statistical advantage of using large numbers with the advantage of interpreting the data as a normal distribution as verified by the chi square test application of the procedure to ferritic microstructures representative of best and worst case conditions indicates that accuracies on the order of 3 percent at a 95 percent confidence level can be achieved in addition the procedure is sensitive enough to distinguish a randomly mixed duplex grain structure the measurements associated with a two phase microstructure can be more precisely quantified through determination of volume fractions using a pp measurement based on the use of an appropriate grid network the coefficient of variation statistic and the poisson distribution the analysis is demonstrated for an a priori system for which the percent accuracy and confidence level can be specified for the volume fraction measurement simply from calculation of the average value for pp
